FORMAL BARYCENTER SPACES WITH WEIGHTS: 
THE EULER CHARACTERISTIC

SADOK KALLEL

Abstract. We compute the Euler characteristic with compact supports $\chi_c$ of the formal barycenter spaces with weights of some locally compact spaces, connected or not. This reduces to the topological Euler characteristic $\chi$ when the weights of the singular points are less than one. As foresighted by Andrea Malchiodi, our formula is related to the Leray–Schauder degree for mean field equations on a compact Riemann surface obtained by C.C. Chen and C.S. Lin.

1. Statement of the main result

Given a space $X$, we will write $B_k(X)$ for the space of formal barycenters of $k$ points in $X$ [11]. By construction there are inclusions $B_k(X) \hookrightarrow B_{k+1}(X)$ for all $k$ and we will write $B(X)$ the direct limit. This is known to be a contractible space if $X$ is of the homotopy type of a CW.

Let $Q_r := \{y_1, \ldots, y_r\} \subset X$ be a fixed finite set of “singular points” in $X$. We assign to every $x \in X$ a weight

$$w(x) = \begin{cases} 
1 & \text{if } x \not\in Q_r, \\
w_i & \text{if } x = y_i,
\end{cases}$$

Key words and phrases. Euler characteristic; compact supports; Leray–Schauder degree; stratification.
where \( w_i > 0 \). Let \( \rho \) be any positive number and define the set

\[
B^Q_\rho(X) = \left\{ \sum_i t_i x_i \in B(X) \left| \sum_i w(x_i) \leq \rho \right. \right\}
\]

This is topologized as a subspace of \( B(X) \) (see Section 2). If \( w_i = 1 \) for all \( i \), the singular points are “invisible” (i.e. they cease to be singular) and \( B^Q_\rho(X) = B_{[\rho]}(X) \), where \([\rho]\) is the greatest integer less or equal to \( \rho \) (with \([ \cdot ]\) being the floor function).

The formal barycenter spaces with weights play nowadays a significant role in geometric analysis. They were introduced in [4] in order to study singular Liouville equations arising in the problem of prescribing the Gaussian curvature and the appearance of conical singularities on compact Riemann surfaces under a conformal change of the metric. The weighted barycenter spaces come with filtration terms that relate to low sublevels of a \( C^1 \)-functional whose Euler-Lagrange equation is the Liouville type equation. The non-contractibility of the weighted barycenter spaces implies a change of topology in the sublevels from which the existence of solutions is deduced. A conjecture about the contractibility of \( B^Q_\rho(X) \) is stated in the case \( X = \Sigma \) is a closed Riemann surface, and this conjecture is addressed in [3]. The computation of the Euler characteristic that we provide in this note gives precise, albeit weaker conditions on the contractibility of \( B^Q_\rho(X) \) for general \( X \), connected or not, compact or not. We expect that this result, in the case when \( X \) is a proper smooth (not necessarily connected) subset of a compact Riemann surface \( \Sigma \), can enable one to determine the Leray-Schauder degree formula for the singular Liouville equation appearing when the prescribed curvature is sign-changing, a problem recently addressed in [7], extending the computation done in [5] for positive curvatures.

Throughout the paper, \( \chi \) will denote the topological Euler–Poincaré characteristic, and \( \chi_c \) the Euler characteristic with compact support (see Section 3). When \( X \) is connected, and there are no singular weights so that \( Q_r = \emptyset \), the Euler characteristic of the barycenter spaces has been computed for general polyhedral spaces in [11]:

\[
(1.2) \quad \chi_{B_k}(X) = 1 - \binom{k - \chi}{k} = 1 - \frac{1}{k!}(1 - \chi)(2 - \chi)\ldots(k - \chi).
\]

It turns out that this formula is still valid for disconnected spaces (Section 5) and even if we replace \( \chi \) by \( \chi_c \) everywhere in the formula (Remark 1.4).

The main contribution of this paper is to compute \( \chi_c(B^Q_\rho(X)) \) for a general family of spaces \( X \), not necessarily connected, and from there deduce the topological Euler characteristic \( \chi \) for many cases of interest (Corollary 1.2).

We define a basic space to be a connected space which is either a finite CW complex or the complement of a subcomplex in a finite CW complex. We recall that \( X \subset Z \) is locally closed (or “LC”) if it is open in its closure (see Section 3).
A typical example we consider in this paper is when $X$ is the interior of a manifold with boundary. Denote by $\mathcal{P}([1, \ldots, r])$ (resp. $\mathcal{P}^*(\{1, \ldots, r\})$) the power set of all subsets of $\{1, \ldots, r\}$ (resp. those excluding the empty set).

**Theorem 1.1.** Let $X$ be a finite union of basic spaces and write $\chi_c = \chi_c(X)$ the Euler characteristic with compact supports of $X$. Let $p_i \in X$, $1 \leq i \leq r$ be the singular points with weights $w_i > 0$, and let $\rho > 0$. Then

$$
\chi_c(B^r\rho_c(X)) = 1 - \left(\frac{|\rho| - \chi_c + r}{|\rho|}\right) + \sum_{\{i_1, \ldots, i_k\} \in \mathcal{P}^*(\{1, \ldots, r\})} (-1)^k\left(\frac{|\rho - w_{i_1} - \ldots - w_{i_k}| - \chi_c + r}{|\rho - w_{i_1} - \ldots - w_{i_k}|}\right)
$$

with the understanding that binomial coefficients where $|\rho - w_{i_1} - \ldots - w_{i_k}| < 0$ are set to zero.

When $r = 0$ (in this case the bottom summation term in the formula above is set to zero) or, when all $w_i$ are equal to 1 (in which case the $p_i$'s cease to be singular), one recovers the formula (1.2). Binomial coefficients can be computed in the case of negative integer entries and they have integral values (Remark 4.6). From Theorem 1.1, we can deduce the topological Euler characteristic $\chi B^Q\rho_c(X)$ as a function of $\chi := \chi(X)$ in the following two relevant cases.

**Corollary 1.2.** Assume $w_i \leq 1$ for all $i$. If $X$ is compact or if $X$ is the interior of an even dimensional manifold with boundary (or a union of those), then $\chi(B^Q\rho_c(X)) = \chi_c(B^Q\rho_c(X))$. In other words, the topological Euler characteristic of $B^Q\rho_c(X)$ is given by the formula in Theorem 1.1 after replacing $\chi_c$ by $\chi$ everywhere in the formula.

**Proof.** When $X$ is compact and the $w_i \leq 1$ for all $i$, $B^Q\rho_c(X)$ is compact and the claim is immediate since $\chi_c$ and $\chi$ agree on compact spaces. When $X$ is the interior of a manifold with boundary $\overline{X}$, then $X$ is open in $\overline{X}$, and the formula applies. If the manifold dimension is even, the Euler characteristic of the boundary is zero (being that of an odd closed manifold) and so by definition (see Section 3) $\chi_c(X) = \chi(\overline{X}) - \chi(\partial\overline{X}) = \chi(\overline{X}) = \chi_c(\overline{X})$ (by compactness of $\overline{X}$). The formula in Theorem 1.1 gives that $\chi_c(B^Q\rho_c(X)) = \chi_c(B^Q\rho_c(\overline{X}))$. By compactness of this barycenter space, this in turn is equal to $\chi(B^Q\rho_c(\overline{X}))$ so that

$$
\chi_c(B^Q\rho_c(X)) = \chi(B^Q\rho_c(\overline{X}))
$$

But a manifold with boundary $\overline{X}$ is homotopy equivalent to its interior $\overline{X} \simeq X$ via a homotopy $H$ that is supported in a collar. Since the $p_i$'s are in $X$ and can be considered to be away from the collar (after applying a homeomorphism if necessary), the homotopy $H$ can be extended to a homotopy equivalence $B^Q\rho_c(\overline{X}) \simeq B^Q\rho_c(X)$, and the claim follows. \qed
Remark 1.3. In the formula of Theorem 1.1, we can regard the term
\[
\left(\frac{|\rho| - \chi_c + r}{|\rho|}\right)
\]
as the contribution of \(\emptyset \in \mathcal{P}(\{1, \ldots, r\})\). In other words, if for \(I = \{i_1, \ldots, i_k\} \subset \{1, \ldots, r\}\), we set \(w_I = \sum_{j=1}^{k} w_{i_j}\), with the convention that when \(I = \emptyset\), \(w_I = 0\) and the cardinality \(|I| = 0\); then our formula takes the more succinct form
\[
\chi_c(B^Q_{\rho}(X)) = 1 - \sum_{I \in \mathcal{P}(\{1, \ldots, r\})} (-1)^{|I|} \left(\frac{|\rho| - w_I - \chi_c + r}{|\rho| - w_I}\right).
\]

Remark 1.4. Interestingly and when there are no critical points, we see that \(\chi_c(B_k(X)) = 1 - \binom{k - \chi_c}{k}\), which means that the formula computing \(\chi_c(B_k(X))\) is similar to (1.2).

Example 1.5. When \(r = 1\) the sum is over \(\emptyset\) and \(\{1\}\), and we obtain
\[
(1.3) \quad \chi_c(B^Q_{\rho}(X)) = 1 - \left(\frac{|\rho| - \chi_c + 1}{|\rho|}\right) + \left(\frac{|\rho| - w_1 - \chi_c + 1}{|\rho| - w_1}\right).
\]
We can check this formula against special cases. Write \(\rho = |\rho| + \varepsilon\), \(0 \leq \varepsilon < 1\).

\[
B^Q_{\rho}(X) = \begin{cases} 
B_{|\rho|}(X) & \text{if } \varepsilon < w_1 < 1 \ (\text{i.e. } |\rho - w_1| = |\rho| - 1), \\
\text{contractible} & \text{if } w_1 \leq \varepsilon \ (\text{i.e. } |\rho - w_1| = |\rho|).
\end{cases}
\]
This is consistent with the Euler characteristic computation since when \(\varepsilon < w_1 < 1\),
\[
\chi(B^Q_{\rho}(X)) = 1 - \left(\frac{|\rho| - \chi_c + 1}{|\rho|}\right) + \left(\frac{|\rho| - \chi_c}{|\rho| - 1}\right) = 1 - \left(\frac{|\rho| - \chi_c}{|\rho|}\right)
\]
and this recovers the formula in Remark 1.4. When \(w_1 \leq \varepsilon\) however, \(|\rho - w_1| = |\rho|\) so that in (1.3), \(\chi_c(B^Q_{\rho}(X)) = 1\) always. Note that the weighted barycenter space is contractible, but this is in general not enough to justify that \(\chi_c = 1\).

Example 1.6. When \(r = 2\) the sum is over \(\emptyset\), \(\{1\}\), \(\{2\}\) and \(\{1, 2\}\), so that
\[
\chi_c(B^Q_{\rho}(X)) = 1 - \left(\frac{|\rho| - \chi_c + 2}{|\rho|}\right) + \left(\frac{|\rho| - w_1 - \chi_c + 2}{|\rho| - w_1}\right) + \left(\frac{|\rho - w_2| - \chi_c + 2}{|\rho - w_2|}\right) - \left(\frac{|\rho - w_1 - w_2| - \chi_c + 2}{|\rho - w_1 - w_2|}\right).
\]
Here too, the various homotopy types for \(B^Q_{\rho}(X)\) can be described (see Section 6).

Remark 1.7. To help check the validity of the formula in Theorem 1.1, there are two fundamental properties that must be satisfied:
(a) Under the condition $w_k \leq \rho < w_{k+1} \leq \ldots \leq w_r$ we must have

$$\chi_c(B^Q_r(X)) = \chi_c(B^Q_r(X - Q_{r-k})).$$

This identity is already true at the level of spaces; i.e. $B^Q_r(X) = B^Q_r(X - Q_{r-k})$ under the stated condition. In particular, if $\rho < w_i$ for all $i$, then

$$\chi_c(B^Q_r(X)) = 1 - \left(\lfloor \rho \rfloor - \chi_c + r\right) = \chi_c(B_{\lfloor \rho \rfloor}(X - Q_r)).$$

The last equality follows from the fact that under the stated conditions,

$$\chi_c(X \setminus Q_r) = \chi_c(X) - r.$$

(b) The second fundamental property is that if $w_{i_1} = \ldots = w_{i_k} = 1$, then the points $p_{i_1}, \ldots, p_{i_k}$ are not singular anymore and $B^Q_r(X) = B^Q_{r-k}(X)$, so that

$$\chi_c(B^Q_r(X)) = \chi_c(B^Q_{r-k}(X)).$$

This is also verified by our formula.

The formula in Theorem 1.1 is intimately related to the Chen–Lin degree $d_\rho$ (see [5]) as we mentioned earlier.

Corollary 1.8. Let $X$ and $Q_r$ as in Theorem 1.1. Consider the Chen–Lin generating series

$$g(x) = (1 + x + x^2 + \ldots)^{-\chi_c + r} \prod_{j=1}^r (1 - x^{w_j})$$

and write it in powers of $x$ as in

$$g(x) = 1 + b_1 x^{n_1} + b_2 x^{n_2} + \ldots + b_k x^{n_k} + \ldots$$

where $1 \leq n_1 < n_2 < \ldots$. Suppose $n_k \leq \rho < n_{k+1}$. Then

$$\chi_c(B^Q_r(X)) = - \sum_{j=1}^k b_j = 1 - d_\rho.$$

Proof. One can give the proof right away and it is combinatorial. We have the expression, for $m > 0$,

$$(1 + x + x^2 + \ldots)^m = 1 + \binom{m}{1} x + \binom{m+1}{2} x^2 + \ldots = \sum_{n=0}^{\infty} \binom{m+n-1}{n} x^n$$

based on the identity

$$1 + \binom{m}{1} + \binom{m+1}{2} + \ldots + \binom{m+n-1}{n} = \binom{m+n}{n}.$$
Remark 4.6 explains why both formulas above are valid for all integers \( m \). In fact \((1 + x + x^2 + \ldots)^m = (1 - x)^{-m}\) if \( m \) is negative. So starting with (1.4), we can write

\[
(1 + x + x^2 + \ldots)^{-\chi_c + r} = \sum_{n=0} \binom{-\chi_c + r + n - 1}{n} x^n.
\]

Multiplying this by \( \prod(1 - x^{w_i}) \) we get the series

\[
g(x) = 1 + b_1 x^{n_1} + b_2 x^{n_2} + \ldots + b_k x^{n_k} + \ldots
\]

Let \( i_1 \leq \ldots \leq i_k \) be a sequence such that \( w_{i_1} + \ldots + w_{i_k} \leq \rho \), and let \( i \) be the smallest integer such that \( i + w_{i_1} + \ldots + w_{i_k} > \rho \) (that is, \( i = 1 = [\rho - w_{i_1} - \ldots - w_{i_k}] \)). Any such sequence contributes to the coefficients of \( g(x) \) via the terms with exponents

\[
x^{w_{i_1} + \ldots + w_{i_k}}, x^{1 + w_{i_1} + \ldots + w_{i_k}}, \ldots, x^{i-1 + w_{i_1} + \ldots + w_{i_k}}.
\]

Here the term \((-1)^k x^{w_{i_1} + \ldots + w_{i_k}}\) comes evidently from the product \( \prod(1 - x^{w_i}) \) and the factor \( x^j \) in \( x^j x^{w_{i_1} + \ldots + w_{i_k}} \) comes from \((1 + x + x^2 + \ldots)^{-\chi_c + r}, \) with the coefficient \((-\chi_c + r + j - 1)^{k-1}\). The total contribution from these exponents to the sum \( \sum_{j=1}^k b_j \) is therefore the sum of their coefficients. To recap, the sequence \( i_1 \leq \ldots \leq i_k \) with \( i - 1 = [\rho - w_{i_1} - \ldots - w_{i_k}] \) contributes to \( \sum_{j=1}^k b_j \) the term

\[
(-1)^k \left[ 1 + \binom{-\chi_c + r}{1} + \binom{-\chi_c + r + 1}{2} + \ldots + \binom{-\chi_c + r + i - 1 - 1}{i-1} \right]
\]

which is equal according to (1.5) to

\[
(-1)^k \binom{-\chi_c + r + i - 1}{i - 1} = (-1)^k \binom{[\rho - w_{i_1} - \ldots - w_{i_k}] - \chi_c + r}{i - 1}.
\]

Adding these over all sequences \( i_1 \leq \ldots \leq i_k \) with the property that \( w_{i_1} + \ldots + w_{i_k} \leq \rho \) gives the desired identity

\[
d_\rho = 1 + \sum_{j=1}^k b_j = 1 - \chi_c.
\]

\[\square\]

**Notation 1.9.** Throughout this note we make the assumption that \( B^0 = B \), \( B_0(X) = \emptyset \) and that \( X \ast \emptyset = X \).

2. Conical subspaces

The formal barycenter spaces \( B_n(X) \) are topologized as quotients of symmetric joins. An element there, also called a “configuration”, is a (formal) finite abelian sum \( \sum_{i=1}^N t_i x_i \), with \( \sum t_i = 1 \), \( t_i \geq 0 \), with the identifications \( t_i x + t_j x = (t_i + t_j) x \) and, if \( t_i = 0 \), the corresponding entry is suppressed (see [11] and [4]).
We will make heavy use of the following construction discussed in [1], [3]. For $A$ closed in $X$, define

$$B_n(X, A) = B_n(X) \cup \left\{ \sum t_i x_i \in B_{n+1}(X) \mid x_i \in A \text{ for some } i \right\}.$$ 

This is the space consisting of all configurations with at most $n$ points in $X \setminus A$ but possibly longer configurations if one of the points is in $A$. The following is clear:

- $B_0(X, A) = A$.
- $B_n(X, A_1) \cup \ldots \cup B_n(X, A_k) = B_n(X, \bigcup A_i)$.

We can extend this definition as follows.

**Definition 2.1.** For pairs of spaces $(X, A_i)$, define

$$B_n(X, A_1, \ldots, A_k) = \left\{ t_1 x_1 + \ldots + t_n x_n + s_1 a_1 + \ldots + s_k a_k \in B_{n+k}(X) \mid a_j \in \bigcup A_i, \right.$$ 

$$\left. \sum t_i + \sum s_j = 1, \ t_i, s_j \geq 0 \right\}.$$

This consists of configurations in $B_{n+k}(X)$ having at most $n$ points in $X - \bigcup A_i$. Again $B_0(X, A_1, \ldots, A_k) = B_k(\bigcup A_i)$. These spaces are closed if the $(X, A_i)$ are closed pairs. By abuse of notation we write $A_i = \{ p_i \}$ is a singleton.

Our definition coincides with that in ([4, §3]) who adopt instead the notation $X^{n,k}_{i_1,\ldots,i_k}$ for our conical spaces $B_n(X, p_{i_1}, \ldots, p_{i_k})$.

**Lemma 2.2.** The conical subspaces $B_n(X, p_1, \ldots, p_k)$ are always contractible as soon as $k \geq 1$.

**Proof.** We have an inclusion $B_n(X, p_1, \ldots, p_k) \subset B_{n+k-1}(X, p_1)$, and the deformation retraction of $B_{n+k-1}(X, p_1)$ to $p_1$ restricts to a deformation retraction of $B_n(X, p_1, \ldots, p_k)$. □

The weighted barycenter spaces $B^Q_p(X)$ only depend on the homeomorphism type of $X$. There is a major difference between the cases when the weights $w_i$ are smaller or bigger than one. In the former case, the spaces behave like “quotients”, while in the latter case they behave like “complements”. For instance, consider one singular point $p$ with weight $w$, and let $X$ be the unit disk $D$ in $\mathbb{R}^n$. If $w > 1$, then $B^Q_1(D) = D - \{ p \}$, and the homotopy type depends on the dimension of $D$.

When the weights $w_i$ are $< 1$, it is possible to describe $B^Q_p(X)$ as a colimit of a diagram of spaces of the form $B_*(X)$ or $B_*(X, p_{i_1}, \ldots, p_{i_k})$. 
Lemma 2.3. Let \( Q = \{p_1, \ldots, p_r\} \), \( \Omega = \{1, \ldots, r\} \), \( w(p_i) = w_i \) and suppose \( 0 < w_i < 1 \) for all \( i \in \Omega \). There is a colimit decomposition
\[
B^Q_\rho(X) = \bigcup_{\{i_1, \ldots, i_k\} \subset \Omega} B_{\rho - w_{i_1} - \ldots - w_{i_k}}(X, p_{i_1}, \ldots, p_{i_k}).
\]

We can refine this union by only considering the maximal conic subspaces making up the union. As indicated by ([3, Definition 2.1]), \( B_a(X, p_{i_1}, \ldots, p_{i_k}) \) includes in \( \bigcup_{j \in \{1, \ldots, k\}} B_{\rho - w_{i_j}}(X, p_{i_j}) \) if \( n \leq m \) and \( \{i_1, \ldots, i_r\} \) splits into a subset in \( \{j_1, \ldots, j_s\} \) and another subset of cardinality \( \leq m - n \). Here \( B_a(X, p_{i_1}, \ldots, p_{i_k}) \) is maximal in \( B^Q_\rho(X) \) if it is not contained in a larger conic subspace.

Example 2.4. Let \( \rho = 4.5 \). Suppose we have 3 singular points with weights \( w_1 = 0.3 \), \( w_2 = 0.4 \), \( w_3 = 0.6 \), then
\[
B^Q_\rho(X) = B_4(X, p_1) \cup B_4(X, p_2) \cup B_3(X, p_1, p_2, p_3).
\]
All subspaces in the union are maximal subspaces.

Example 2.5. When \( r = 1 \), with a single singular point \( p \) of weight \( 0 < w \leq 1 \), then
\[
B^Q_\rho(X) = B_{|\rho|}(X) \cup B_{|\rho - w|}(X, p).
\]
One can see immediately that \( B^Q_\rho(X) = B_{|\rho|}(X) \) if \( |\rho - w| < |\rho| \) since in that case \( B_{|\rho - w|}(X, p) \subset B_{|\rho|}(X) \), and that \( B^Q_\rho(X) = B_{|\rho|}(X, p) \) is contractible if \( |\rho - w| = |\rho| \) (Example 1.5).

Example 2.6. Suppose \( r = 2 \), \( p_1 \), \( p_2 \) having weights \( w_1 \), \( w_2 \). In the case \( w_1, w_2 \leq \rho - |\rho| = \varepsilon \), \( w_1 + w_2 > \varepsilon \), we can have a configuration of length \( |\rho| + 1 \) provided the configuration contains \( p_1 \) or \( p_2 \), but no configuration can be of length \( |\rho| + 2 \). This means that
\[
B^Q_\rho(X) = B_{|\rho|}(X, p_1) \cup B_{|\rho|}(X, p_2)
\]
Other descriptions occur depending on the choices of \( w_1, w_2 \) (see Section 6). Notice that in the present case
\[
B_{|\rho|}(X, p_1) \cap B_{|\rho|}(X, p_2) = B_{|\rho|}(X) \cup B_{|\rho| - 1}(X, p_1, p_2).
\]
It is always true that the intersection of conical subspaces is again a union of conical subspaces. This fact is crucial when it comes to determining some quotients and some homotopy types.

We next list the main properties for the conic spaces needed in our computation of the Euler characteristic. We restrict below to when \((X, A)\) is a CW-pair.

Lemma 2.7. Assume \( n \geq 1 \). The following hold:

(a) \( B_n(X, A) \) is contractible if \( A \) is contractible. In particular, \( B_n(X, p) \) is contractible.
(b) (See [1]) Let \(A\) be a closed subspace of \(X\). Then

\[
\frac{B_n(X)}{B_{n-1}(X,A)} \simeq B_n(X/A).
\]

(c) If \(X\) is contractible, then \(B_n(X/A) \simeq \Sigma B_{n-1}(X,A)\) where \(\Sigma\) means suspension.

**Proof.** (a) is Lemma 2.2. For the second claim, notice that

\[
\frac{B_n(X)}{B_{n-1}(X,A)} = \frac{B_n(X/A)}{B_{n-1}(X/A,p)},
\]

where \(p\) is the preferred basepoint in \(X/A\). Since \(B_{n-1}(X/A,p)\) is contractible we obtain the homotopy equivalence in claim (b). The simplest example here is when \(n = 1\), \(B_0(X,A) = A\), \(B_1(X) = X\) and the quotient is \(X/A\).

Claim (c) is a direct consequence of (b) and the fact that \(B_n(X)\) is also contractible. \(\square\)

**Example 2.8.** When \(X = D\) is a closed \(m\)-dimensional ball with boundary \(\partial D = S^{m-1}\), \(B_n(X)\) is contractible since \(D\) is contractible, so Lemma 2.7(c) implies that \(B_n(S^m) \simeq \Sigma(B_{n-1}(D,S^{m-1}))\).

### 3. The compactly supported Euler characteristic

The compactly supported Euler characteristic \(\chi_c\), sometimes called the “combinatorial” Euler characteristic, is defined for locally compact spaces and has the property that for any disjoint decomposition of \(X = \bigsqcup X_i\) where each \(X_i\) is a locally closed subspace of \(X\),

\[
\chi_c(X) = \sum \chi_c(X_i).
\]

As is common, we reserve the word “stratification” \(\{X_i\}\) for \(X\) if \(X\) is a disjoint union of the \(X_i\)’s and all \(X_i\)’s are locally closed in \(X\).

**Remark 3.1.** Being locally closed in a topological space \(X\) has various equivalent definitions (see [8, Proposition 1]). Here’s conveniently the list of equivalences: \(A\) is locally closed in \(X\) if \(A = U \cap \text{cl} A\) for some open set \(U\) if \(\text{cl} A \setminus A\) is closed if \(A \cup (X \setminus \text{cl} A)\) is open. It seems more convenient to think in terms of the third equivalence: \(A\) is LC in \(X\) if \(\text{cl} A \setminus A\) is closed.

The above additivity formula for \(\chi_c\) makes it a very computable characteristic. Its drawback is that it is not an invariant of homotopy type. For example when \(D\) is the open unit disk, then \(\chi(D) = 1\) if \(D\) is even dimensional, and \(\chi(D) = -1\) if \(D\) has odd dimension. In particular, if \(X\) is contractible, \(\chi_c(X)\) is not necessarily 1. As expected, \(\chi_c(X) = \chi(X)\) if \(X\) is compact.
If $X$ is open in a compact Hausdorff space $\overline{X}$, in particular if $X$ is the complement of a subcomplex in a finite CW-complex $\overline{X}$, then

$$\chi_c(X) = \chi(\overline{X}) - \chi(\overline{X} \setminus X) = \chi\left(\frac{\overline{X}}{\overline{X} \setminus X}\right) - 1.$$  

The 1 is subtracted to compensate for one less factor in $H_0$. This is the formula we use to compute $\chi_c$ throughout the paper.

**Definition 3.2.** We say that $X$ admits a “BM-compactification” $\overline{X}$ if $X$ is a finite CW complex and $\overline{X} \setminus X$ is a closed subcomplex (cf. [9, §10] and [6, §2.6]). If $X$ is compact, then $\overline{X} = X$.

**Example 3.3 ([12]).** If $X$, $Y$ admit BM-compactifications, then

$$\chi_c(X \ast Y) = \chi_c(X) + \chi_c(Y) - \chi_c(X)\chi_c(Y)$$

either $X$ or $Y$ is compact, or both. Also and as a consequence of this formula, we find that

$$\chi_c(\Sigma^kX) = 1 + (-1)^k(\chi_c(X) - 1),$$

where $\Sigma^kX := S^k \ast X$ is the suspension iterated $k$ times of $X$. When $k$ is even $\chi_c(\Sigma^kX) = \chi_c(X)$ and when $k$ is odd $\chi_c(\Sigma^kX) = 2 - \chi_c(X)$.

**Example 3.4.** This next example is pertinent and discusses the computation of $\chi_c(B^{2\rho}_1(D))$, where $D$ is the open unit disk in $\mathbb{R}^n$, $\rho = \lfloor \rho \rfloor + \varepsilon$ and where the unique singular point $p_1$ at the origin has weight $0 < w_1 \leq \varepsilon$. This is a good illustration of the importance of having the locally closed condition when computing $\chi_c$, and is also some explanation of the peculiarity discussed at the end of Remark 1.5.

Now evidently in this case $B^{2\rho}_1(D) = B_{\lfloor \rho \rfloor}(D, p_1)$ is contractible. Take $\lfloor \rho \rfloor = 1$, then $B_1(D, p_1)$ consists of all configurations of the form $t_1x + t_2p_1$, $t_1 + t_2 = 1$. This is the cone on $D$ but we must identify all points of the form $t_1p_1 + t_2p_1 \sim p_1$, so $B_1(D, p_1)$ is homeomorphic to the reduced cone $cD$ obtained from the cone by collapsing the segment $[v, 0]$ to 0, where $v$ is the vertex of the cone, and 0 the origin of $D$. This space is stratified as follows. We will specify the dimension by writing $D^n$ for the $n$-dimensional open disk. Its cone with vertex $v$ can be stratified as $D^{n+1} \sqcup \{v\} \sqcup D^n$. The reduced cone $cD$ has then a locally closed stratification of the form (up to homeomorphism)

$$cD = (D^{n+1} \setminus L) \sqcup D^n,$$

where $L$ is a diameter in the open disk $D^{n+1}$ (note already that $v$ has been identified with 0 $\in D^n$ in this decomposition).

A BM-compactification of $D^{n+1} \setminus L$ is the closed disk $\overline{D}^{n+1}$ and $\overline{D}^{n+1} \setminus (D^{n+1} \setminus L)$ is the sphere $S^n$ together with a diameter attached, so it is homotopy
equivalent to $S^n \vee S^1$. We can then write
\[
\chi_c(B_1(D, p_1)) = \chi_c(cD) = \chi_c(D^{n+1} \setminus L) + \chi_c(D^n) \\
= \chi(D^n) - \chi(S^n \vee S^1) + \chi(D^n) - \chi(S^{n-1}) \\
= 1 - (\chi(S^n) - 1) + 1 - \chi(S^{n-1}) = 1,
\]
so this is always 1 as predicted by Theorem 1.1. The way we compute this in Section 4.1 is by using a slightly different stratification which is better adapted to the general situation.

3.1. Topology. The topology of $B^Q(X)$ can be subtle, especially when dealing with pushouts and compactifications. We make some observations and draw attention to subtle issues related to the topology of barycenter spaces.

If $A \subset X$ is a closed subspace, then $B_n(A)$ is closed in $B_n(X)$. This is not generally true if we replace closed by open. Take $A = (0, 1)$ and $X = [0, 1]$. The sequence $\left(\left(1 - \frac{1}{n}\right)x_1 + \frac{1}{n}x_2\right)$, with $x_1 = \frac{1}{2}$ and $x_2 = 1$,
is in $B_2([0,1]) \setminus B_2((0,1))$ and converges to $x_1 \in (0,1) = B_1(0,1) \subset B_2(0,1)$, which means that $B_2(A)$ cannot be open in $B_2(X)$. That the statement is true for closed sets and not open sets is a consequence of the fact that generally $B_n(X) \setminus B_n(A)$ is not $B_n(X \setminus A)$. In fact and as sets
\[
B_n(X) = B_n(X \setminus A) \cup B_{n-1}(X, A).
\]

This union is not a pushout or an adjunction space construction ([2, Section 4.5]). Indeed, the intersection of both factors in the union is $B_{n-1}(X \setminus A)$. The union doesn’t have the quotient topology of the corresponding adjunction space since there is part of the boundary of $B_n(X \setminus A)$ intersecting $B_{n-1}(X, A)$ and yet not being in $B_{n-1}(X \setminus A)$.

Notation 3.5 (and terminology). If $X$ is compact, then we write $\overline{X} = X$, and if not, then $\overline{X}$ is the closure of $X$, and $(\overline{X}, X)$ is a BM-compactification. In this latter case, we write conveniently $\partial \overline{X} := \overline{X} \setminus X$.

Lemma 3.6. Let $Q_r = \{p_1, \ldots, p_r\} \subset X$, and suppose $X$ is basic. Then $B_n(X - Q_r) - B_{n-1}(X - Q_r)$ is locally closed in $B_n(\overline{X})$, and this pair is a BM-compactification.

Proof. A configuration $\sum t_ix_i$ in $B_n(X - Q_r) - B_{n-1}(X - Q_r)$ approaches its boundary in $B_n(\overline{X})$ if one $x_i$ approaches $Q_r \cup \partial \overline{X}$, or if a $t_i$ approaches 0 or if two points of the configuration approach each other. In other words and more
precisely, we have
\[
B_n(X) \setminus (B_n(X - Q_r) - B_{n-1}(X - Q_r)) = (B_n(X) \setminus B_n(X - Q_r)) \cup B_{n-1}(X - Q_r) = B_{n-1}(X - Q_r) = B_{n-1}(X - Q_r).
\]
This is closed in \(B_n(X)\) which is compact and is the closure of \(B_n(X - Q_r) - B_{n-1}(X - Q_r)\).

The lemma above is what enables us to compute \(\chi_c\) for such complements in Section 4 next.

Another remark pertaining to topology is to take \(A, B\) disjoint in \(X\). For example can have \(B = X \setminus A\). Then \(B_i(A) * B_j(B)\) is a subset of \(B_{i+j}(X)\), meaning the topology of the join coincides with the induced topology. The closure of \(B_i(A) * B_j(B)\) in \(B_{i+j}(X)\) is homeomorphic to \(B_i(\overline{A}) * B_j(\overline{B})\) if and only if however the closures are disjoint \(A \cap B = \emptyset\).

**Example 3.7.** Consider the stratum in \(B^Q_r(X)\) consisting of all configurations having exactly \(k\) singular points \(p_1, \ldots, p_k\) appearing in the configuration (i.e. having non-zero coefficients), and no other singular points. Let’s denote this stratum by \(B_n(X - Q_r) \ast B_k\{p_1, \ldots, p_k\}\). A configuration in \(B_n(X - Q_r) \ast B_k\{p_1, \ldots, p_k\}\) is then of the form
\[
\sum_{i=0}^{n} l_i x_i + s_1 p_1 + \ldots + s_k p_k, s_i \neq 0, \quad x_i \notin Q_r.
\]
This stratum as a subspace of \(B^Q_r(X)\) can be written as
\[
(3.4) \quad B_n(X - Q_r) \ast B_k\{p_1, \ldots, p_k\} := B_n(X - Q_r) * B_k\{p_1, \ldots, p_k\}
- B_n(X - Q_r) * B_{k-1}\{p_1, \ldots, p_k\}
\]
Its \(\chi_c\)-computation can therefore be deduced from Lemma 3.6 (see Proposition 4.5).

**4. Proof of Theorem 1.1**

This proof is broken in several steps. We recall throughout that \(B_0(X) = \emptyset\) and that \(X * \emptyset = X\). Notation and terminology are as in Definition 3.2 and Notation 3.5.

**Lemma 4.1.** Let \(X\) be a basic set. Then \(\chi_c(B_n(X)) = 1 - \binom{n-k}{n}\).

**Proof.** The proof is carried out for \((\overline{X}, X)\) pair, the case when \(X\) compact is known. The BM-compactification of \(B_n(X)\) is certainly not \(B_n(\overline{X})\) as indicated in Lemma 3.6. We therefore need to stratify \(B_n(X)\) as follows. Set
\[
X_n := B_n(X) - B_{n-1}(X)
\]
so that in light of the aforementioned lemma, \( \overline{X}_n = \mathcal{B}_n(\overline{X}) \) and \( \overline{X}_n \setminus X_n = \mathcal{B}_{n-1}(\overline{X}, \partial \overline{X}) \). By Lemma 2.7 we have

\[
\chi_c(\overline{X}_n) = \chi_c(\mathcal{B}_n(\overline{X})) \simeq \mathcal{B}_n(\overline{X})
\]

and we get immediately for \( n \geq 2 \)

\[
(4.1) \quad \chi_c(X_n) = \chi_c(\overline{X}_n \setminus X_n) - 1 = \chi_c(\mathcal{B}_n(\overline{X})) - 1 = -\left( \frac{n - \chi_c - 1}{n} \right)
\]

with the last equality obtained from (1.2) and the identity (3.1).

To get to \( \chi_c(\mathcal{B}_n(X)) \) we write

\[
\mathcal{B}_n(X) = (\mathcal{B}_n(X) \setminus \mathcal{B}_{n-1}(X)) \sqcup \cdots \sqcup (\mathcal{B}_2(X) \setminus \mathcal{B}_1(X)) \sqcup X \simeq X_n \sqcup \cdots \sqcup X_1
\]

which is a stratification with locally closed strata, so we can use the additivity of \( \chi_c \) to see that

\[
\chi_c(\mathcal{B}_n(X)) = \sum_{1 \leq i \leq n} \chi_c(X_i)
\]

\[
= -\left( \frac{n - \chi_c - 1}{n} \right) - \left( \frac{n - \chi_c - 2}{n - 1} \right) - \cdots - \left( \frac{\chi_c}{1} \right) \overset{(1.5)}{=} -\left( \frac{n - \chi_c}{n} \right)
\]

which proves the lemma. \( \square \)

**Corollary 4.2.** Let \( X \) be a basic set and \( Q_r \subset X \). Then

\[
\chi_c(\mathcal{B}_n(X - Q_r)) = 1 - \left( \frac{n - \chi_c + r}{n} \right).
\]

The next two lemmas are a preparation for Proposition 4.5.

**Lemma 4.3.** For \( X \) basic and \( Q_r \subset X \), we have

\[
\frac{X}{Q_r \cup \partial X} \simeq \begin{cases} 
\overline{\frac{X}{\partial X}} \vee \bigvee_{r} S^1 & \text{if } \partial \overline{X} \neq \emptyset, \\
X \vee \bigvee_{r-1} S^1 & \text{if } X \text{ compact.}
\end{cases}
\]

This a straightforward consequence of the fact that in a path-connected space, the identification of two points is up to homotopy like the one point union with a circle. The proof is skipped. The analog of this lemma for disconnected spaces is given in Lemma 5.4. The next Lemma is imported from [1].

**Lemma 4.4 ([1, Lemma 5.10]).** Let \( (X, A) \) and \( (Y, B) \) be two connected CW pairs. Then \( (X * Y)/(A * Y) \simeq (X/A) * Y \) and

\[
(X * Y)/(X * B \cup A * Y) \simeq \begin{cases} 
X/A * Y/B & \text{for } A \neq \emptyset, B \neq \emptyset, \\
\Sigma X/A \times Y & \text{for } A \neq \emptyset, B = \emptyset, \\
\Sigma (X \times Y) \vee S^1 & \text{for } A = \emptyset, B = \emptyset,
\end{cases}
\]

where \( X \times Y := (X \times Y)/(x_0 \times Y) \) is the half-smash product.
PROPOSITION 4.5. Again \( X \) basic, \( \emptyset \neq Q_r \subset X \) and \( \chi_c := \chi_c(X) \). For \( k \geq 1 \), define \( B_n(X - Q_r) \circ B_k \{ p_1, \ldots, p_k \} \) as in (3.4). Then
\[
\chi_c(B_n(X - Q_r) \circ B_k \{ p_1, \ldots, p_k \}) = (-1)^{k+1}\binom{n - \chi + r}{n}.
\]

PROOF. We recall that \( B_k Q_k = B_k \{ p_1, \ldots, p_k \} \) is homeomorphic to the \( k - 1 \) dimensional simplex \( \Delta_{k-1} \) and that \( B_{k-1} Q_k \) is its boundary sphere \( \partial \Delta_{k-1} \). Consider, as in Example 3.7, the subspace
\[
X_i = B_i(X - Q_r) \circ B_k Q_k - B_{i-1}(X - Q_r) \circ B_k Q_k.
\]
We clearly have
\[
B_n(X - Q_r) \circ B_k Q_k = X_n \cup \ldots \cup X_0,
\]
where the last two spaces are given by \( X_1 = (X - Q_r) \circ B_k Q_k - B_k Q_k \) and \( X_0 = B_k Q_k = B_k Q_k - B_{k-1} Q_k \) (the interior of a disk of dimension \( k - 1 \)). Note that the first stratum \( X_0 \) is open in \( B_n(X - Q_r) \circ B_k Q_k \). This is a locally closed stratification and
\[
\chi_c(B_n(X - Q_r) \circ B_k Q_k) = \sum_{0 \leq i \leq n} \chi_c(X_i).
\]
The simplest case is when \( n = 0 \) where evidently
\[
(4.2) \quad \chi_c(X_0) = \chi_c(B_k Q_k) = \chi_c(\Delta_{k-1}) = (-1)^{k-1}.
\]
For \( n \geq 1 \), and assuming \( X \) is compact, a BM-compactification for \( X_n \) is given by \( \overline{X}_n = B_n(X) \ast B_k(Q_k) \). The complement of \( X_n \) in \( \overline{X}_n \) is
\[
(B_n(X) \ast B_{k-1}(Q_k)) \cup (B_{n-1}(X, \{ p_1, \ldots, p_r \}) \ast B_k(Q_k)),
\]
so that, from the definition of \( \chi_c \), we have
\[
\chi_c(X_n) = \chi\left(\frac{B_n(X) \ast B_k(Q_k)}{(B_n(X) \ast B_{k-1}(Q_k)) \cup (B_{n-1}(X, \{ p_1, \ldots, p_r \}) \ast B_k(Q_k))}\right) - 1.
\]
The quotient in the first term on the right can be described precisely (Lemma 4.4). For \( k \geq 2 \), this is
\[
(4.3) \quad \chi_c(X_n) = \chi\left(\frac{B_n(X)}{B_{n-1}(X, \{ p_1, \ldots, p_r \}) \ast B_k(Q_k)}\right) - 1
\]
(by Lemma 4.4, first case)
\[
= \chi\left(B_n\left(X \cup \bigvee_{r} S^1\right) \ast S^{k-1}\right) - 1
\]
\[
= \chi\left(\Sigma^k B_n\left(X \cup \bigvee_{r} S^1\right)\right) - 1
\]
\[
\begin{align*}
(3.3) & \quad (\chi \left( \mathcal{B}_n(X \setminus \bigcup S^1) \right) - 1 \\
(4.4) & \quad -(1)^k \left( \frac{n - \chi + r - 1}{n} \right).
\end{align*}
\]

Adding up (4.2) and (4.4), we obtain (in case \( k \geq 2 \))
\[
\chi_c(\mathcal{B}_n(X - Q_r) \ast \mathcal{B}_k(\{p_1, \ldots, p_k\})) = -(1)^k \left( \frac{n - \chi + r - 1}{n} \right)
\]
and this is
\[
-(-1)^k \left( \frac{n - \chi + r}{n} \right)
\]
as desired. This covers the case \( k \geq 2 \).

For the case \( k = 1 \), the exact same steps as in (4.3) apply only that the first step becomes
\[
\chi_c(X_n) = \chi \left( \frac{\mathcal{B}_n(X) \ast p}{\mathcal{B}_n(X) \cup \mathcal{B}_{n-1}(X, Q_r) \ast p} \right) - 1 = \chi \left( \sum \mathcal{B}_n \left( \frac{X}{Q_r} \right) \right) - 1
\]
by the second case of Lemma 4.4. The rest is the same.

To double check the case \( k = 1 \), using Lemma 3.6, we can write
\[
\mathcal{B}_n(X - Q_r) \ast p = \mathcal{B}_n(X - Q_r) \ast p - \mathcal{B}_n(X - Q_r),
\]
so we have a similar stratification by locally closed subsets
\[
X_i = (\mathcal{B}_i(X - Q_r) \ast p \setminus \mathcal{B}_i(X - Q_r)) - (\mathcal{B}_{i-1}(X - Q_r) \ast p \setminus \mathcal{B}_{i-1}(X - Q_r))
\]
for \( i \geq 1 \) and \( X_0 = p \). As before \( \mathcal{B}_n(X - Q_r) \ast p = X_n \cup \ldots \cup X_0 \) and we can compute the \( \chi_c \) of each stratum. Since \( \chi_c(Y \ast p) = 1 \), if \( Y \) has a BM-compactification, see (3.2), we have that \( \chi_c(Y \ast p - p) = 0 \). This gives that
\[
\chi_c(\mathcal{B}_n(X - Q_r) \ast p) = -\sum_{1 \leq i \leq n} \chi_c(\mathcal{B}_i(X - Q_r) \ast \mathcal{B}_{i-1}(X - Q_r)) + \chi(p)
\]
which is what we wanted to prove.

In conclusion, the above calculations give the right answer in the case \( X \) is compact. When \( (X, X) \) is a BM compactification, we have to modify each step of the proof by incorporating a boundary \( \partial X \), keeping in mind that the singular points \( p_j \) are in the interior. The modifications are indicated below, yielding the same final results. For \( k \geq 2 \), we use the same stratification by \( X_n \), only that \( X_n \) will change.
• For \( n \geq 1 \), \( \overline{X}_n = B_n(\overline{X}) * B_k(Q_k) \), and the complement \( \overline{X}_n \setminus X_n \) is
\((B_n(\overline{X}) * B_{k-1}(Q_k)) \cup (B_{n-1}(\overline{X}, \partial \overline{X} \cup \{p_1, \ldots, p_r\}) * B_k(Q_k))\).

• When \( k \geq 2 \), the quotient \( \overline{X}_n / (\overline{X}_n \setminus X_n) \) is up to homotopy
\[ B_n \left( \frac{\overline{X}}{\partial \overline{X}} \vee \bigvee_{i=1}^{r} S^1 \right) * S^{k-1}. \]

Lemma 4.3, and the same computation as in (4.4) yields the same formula
with \( \chi \) replaced by \( \chi_c \).

• For \( k = 1 \), no changes, simply apply (4.1) with \( \chi_c \) instead of \( \chi \).

This concludes the proof if \( X \) is a basic set. \( \square \)

### 4.1. Proof of the main theorem
We derive the formula of Theorem 1.1 for a basic set \( X \) and singular points \( p_1, \ldots, p_r \). We will prove that
\[ \chi_c(B^{Q_r}_\rho(X)) = 1 - \left( \frac{\lfloor \rho \rfloor - \chi_c + r}{\lfloor \rho \rfloor} \right) \]
\[ - \sum_{\{i_1, \ldots, i_r\} \in P^*\{1, \ldots, r\}} (-1)^k \left( \frac{\lfloor \rho - w_{i_1} - \ldots - w_{i_k} \rfloor - \chi_c + r}{\lfloor \rho - w_{i_1} - \ldots - w_{i_k} \rfloor} \right) \]

**Proof.** The key point is to write \( B^{Q_r}_\rho(X) \) as the disjoint union of subspaces
\[ (4.5) \quad B^{Q_r}_\rho(X) = B_{\lfloor \rho \rfloor}(X - Q_r) \sqcup \bigcup_i B_{\lfloor \rho - w_i \rfloor}(X - Q_r) \circ p_i \]
\[ \sqcup \bigcup_{\{i_1, i_2, i_3\}} B_{\lfloor \rho - w_{i_1} - w_{i_2} \rfloor}(X - Q_r) \circ B_2\{p_{i_1}, p_{i_2}\} \]
\[ \sqcup \bigcup_{\{i_1, i_2, i_3\}} \ldots \cup B_{\lfloor \rho - w_{i_1} - \ldots - w_{i_k} \rfloor}(X - Q_r) \circ B_r\{p_1, \ldots, p_r\}. \]

In this notation \( B_{\lfloor \rho \rfloor}(X - Q_r) \circ Z \) is empty if \( i < 0 \), \( B_0(X - Q_r) \circ Z = Z \) and
\( i_n \neq i_m \) if \( n \neq m \). In this disjoint union, notice that if \( p_i \) has weight \( w_i \leq \rho \),
then it appears in the term \( B_{\lfloor \rho - w_i \rfloor}(X - Q_r) \circ p_i \) (and it appears only there) so
everything is accounted for once. We claim that
\[ \chi_c(B^{Q_r}_\rho(X)) = \chi_c(B_{\lfloor \rho \rfloor}(X - Q_r)) \]
\[ + \sum_{\{i_1, \ldots, i_k\}} \chi_c(B_{\lfloor \rho - w_{i_1} - \ldots - w_{i_k} \rfloor}(X - Q_r) \circ B_2\{p_{i_1}, \ldots, p_{i_k}\}) \]
and this sum yields precisely the desired formula in light of Proposition 4.5 and
Lemma 4.2. As pointed out multiple times, the factors
\[ B_{\lfloor \rho - w_{i_1} - \ldots - w_{i_k} \rfloor}(X - Q_r) \circ B_2\{p_{i_1}, \ldots, p_{i_k}\} \]
are not locally closed in \( B^{Q_r}_\rho(X) \) in general, but they are themselves stratified
by strata \( \{ X_i \} \) which are LC in \( B^{Q_r}_\rho(X) \), so \( \chi_c \) is additive on (4.5) and the proof follows. \( \square \)
Remark 4.6. We point out a computational aspect of this formula. Binomial coefficients \( \binom{n}{k} \) can be computed in the case of negative integers \( n \), and non-negative \( k \). One should view \( \binom{X}{k} \) as the rational function

\[
\frac{X(X-1)\ldots(X-(k-1))}{k(k-1)\ldots1},
\]

so substituting \( n \) (any integer) for \( X \) gives that for \( 0 \leq n < k \), \( \binom{n}{k} = 0 \), while for \( n < 0 \) (eg. \([13]\)) \( \binom{n}{k} = (-1)^k \binom{k}{n} \), \( k > 0 \), \( n < 0 \).

We set \( \binom{n}{0} = 1 \) for all \( n \in \mathbb{Z} \). Obviously, we can check that with this definition, the identity in (1.5) remains valid. This is because it is valid at the level of rational functions (replacing \( m \) in the formula by \( X \)). Note that, if \( m = 0 \), all terms on the left of (1.5) are zero but the first term 1. Similarly, (1.4) is valid for all \( m \), and for negative \( m \), \( (1 + x + x^2 + x^3 + \ldots)^m = (1 - x)^{-m} \).

We can then assume the theorem is true for \( Y \). Pick \( p_1 \in Y \) and \( p_2 \in A \), and consider the subspace \( B_n(X, \{p_1, p_2\}) \) of all barycenter configurations containing either \( p_1 \) or \( p_2 \). Then this is a union of two connected spaces

\[
B_n(X, \{p_1, p_2\}) = B_n(X, p_1) \cup B_n(X, p_2)
\]

and these spaces intersect along the subspace

\[
B_n(X) \cup B_{n-1}(X, p_1, p_2)
\]

(recall that \( B_0(X, p_1, p_2) = B_2(\{p_1, p_2\}) \) which is an interval). Since both spaces \( B_n(X, p_i) \) are contractible, their union has the homotopy type of the suspension.
of their intersection and we have

$$\mathcal{B}_n(X, \{p_1, p_2\}) \simeq \Sigma(\mathcal{B}_n(X) \cup \mathcal{B}_{n-1}(X, p_1, p_2))$$

since \(\mathcal{B}_{n-1}(X, p_1, p_2)\) is contractible

$$\simeq \Sigma\left(\frac{\mathcal{B}_n(X)}{\mathcal{B}_n(X) \cap \mathcal{B}_{n-1}(X, p_1, p_2)}\right) \simeq \Sigma\left(\frac{\mathcal{B}_n(X)}{\mathcal{B}_{n-1}(X, \{p_1, p_2\})}\right)$$

by Lemma 2.7 (b)

$$\simeq \Sigma \mathcal{B}_n(X/p_1 \sim p_2) \simeq \Sigma \mathcal{B}_n(Y \vee A).$$

Note that \(Y \vee A\) has one component less than that of \(X\) and \(\chi(Y \vee A) = \chi - 1\), where \(\chi = \chi(X)\). Taking Euler characteristics gives that

$$\chi \mathcal{B}_n(X, \{p_1, p_2\}) = 2 - \chi \mathcal{B}_n(Y \vee A)$$

by induction

$$= 1 + \left(\frac{n - (\chi Y + \chi A - 1)}{n}\right) = 1 + \left(\frac{n - \chi + 1}{n}\right).$$

On the other hand,

$$\frac{\mathcal{B}_n(X)}{\mathcal{B}_{n-1}(X, \{p_1, p_2\})} \simeq \mathcal{B}_n(Y \vee A),$$

and we can use the formula for the quotient \(\chi(A/B) = \chi(A) - \chi(B) + 1\) to write

$$\chi \mathcal{B}_n(Y \vee A) = \chi\left(\frac{\mathcal{B}_n(X)}{\mathcal{B}_{n-1}(X, \{p_1, p_2\})}\right) = \chi \mathcal{B}_n(X) + 1 - \chi \mathcal{B}_{n-1}(X, \{p_1, p_2\})$$

which recombines into

$$\chi \mathcal{B}_n(X) = -1 + \chi \mathcal{B}_{n-1}(X, \{p_1, p_2\}) + \chi \mathcal{B}_n(Y \vee A)$$

$$= 1 + \left(\frac{n - \chi}{n - 1}\right) - \left(\frac{n - \chi + 1}{n}\right) = 1 - \left(\frac{n - \chi}{n}\right).$$

The proof is complete. \(\square\)

5.1. A combinatorial proof of Proposition 5.1. We know that the homology of \(\mathcal{B}_k(X)\) only depends on the homology of \(X\) (a fact more general than Euler characteristics) [11]. The following shows that this is true for disconnected spaces as well.

**Theorem 5.2 ([1])**. Suppose \(X = A \sqcup B\) is the disjoint union of spaces (not necessarily connected). Then, for \(k \geq 2\), \(\mathcal{B}_k(A \sqcup B)\) has the same homology as

$$\mathcal{B}_k(A) \vee \Sigma \mathcal{B}_{k-1}(A) \vee \mathcal{B}_k(B) \vee \Sigma \mathcal{B}_{k-1}B$$

$$\vee \bigvee_{\ell=1}^{k-1} \mathcal{B}_{k-\ell}(A) \ast \mathcal{B}_{\ell}(B) \vee \bigvee_{\ell=2}^{k-1} \Sigma \mathcal{B}_{k-\ell}(A) \ast \mathcal{B}_{\ell-1}(B).$$
Example 5.3. We can describe some homotopy types of some barycenter spaces of disjoint unions:
(a) When \( k = 2 \), \( B_2(A \sqcup B) \) has actually the homotopy type of
\[
B_2(A) \vee \Sigma(A \times B) \vee B_2(B).
\]
(b) When one of the components is contractible, say \( B \simeq p \), then
\[
B_n(A \sqcup B) \simeq B_n(A \sqcup p) = B_n(A) \cup B_{n-1}(A) * p \simeq B_n(A) \vee \Sigma B_{n-1}A.
\]
This last equivalence follows from the fact that we are attaching a cone on \( B_{n-1}(A) \) which is itself contractible in \( B_n(A) \).
(c) For \( k \geq 2 \), it is not hard to check that there is a homotopy equivalence
\[
B_2(A \sqcup \{y_1, \ldots, y_k\}) \simeq B_2(A) \vee \bigvee^{k \choose 2} \Sigma A \vee S^{1} \bigvee^{k\choose 2} S^{1-1}
\]
which is in fact the decomposition in Theorem 5.2 obtained at the level of spaces
(d) It is not always true that when the components are contractible, \( B_k(X) \) is also contractible for \( k \geq 2 \). This only happens when \( k \) is larger (or equal) to the number of components. In fact, if \( X = [n+1] \) is a set consisting of \( n+1 \)-vertices, then \( B_{k+1}([n+1]) \) is the \( k \)-th skeleton of \( n \)-dimensional simplex \( \Delta_n \), and thus is a bouquet of spheres
\[
B_k([n+1]) \simeq \binom{n}{k} S^{k-1}, \quad k \leq n,
\]
which is the notation for a bouquet of that many spheres. This we can recover iteratively as follows:
\[
B_k([n+1]) = B_k([n] \sqcup [1]) \simeq B_k([n]) \vee \Sigma B_{k-1}([n])
\]
\[
\simeq \left( \binom{n-1}{k} + \binom{n-1}{k-1} \right) S^{k-1} = \binom{n}{k} S^{k-1}.
\]
We now derive Proposition 5.1 from Theorem 5.2 easily as follows. By taking \( \chi \) of the wedge decomposition in the theorem, we find that
\[
\chi B_k(A \sqcup B) = \chi B_k A + (2 - \chi B_{k-1} A) + \chi B_k B + (2 - \chi B_{k-1} B)
\]
\[
+ \sum_{\ell=1}^{k-1} \left( \chi B_{k-\ell} A + \chi B_{\ell} B - \chi B_{k-\ell} A \chi B_{\ell} B \right)
\]
\[
+ \sum_{\ell=2}^{k-1} \left( 2 - \chi B_{k-\ell} A - \chi B_{\ell-1} B + \chi B_{k-\ell} A \chi B_{\ell-1} B \right) - 2k.
\]
The term “\(-2k\)” accounts for the wedge points being counted multiple times.
We can set \( \chi_1 = \chi(A) \) and \( \chi_2 = \chi(B) \) and proceed by induction. Replacing
binary coefficients in the above expression we get the identity
\[
\chi_{B_k}(A \sqcup B) = 4 + \binom{k - 1 - \chi_1}{k - 1} - \binom{k - \chi_1}{k} + \binom{k - 1 - \chi_2}{k - 1} - \binom{k - \chi_2}{k} \\
+ \sum_{\ell=1}^{k-1} \left( 1 - \binom{k - \ell - \chi_1}{k - \ell} \binom{\ell - \chi_2}{\ell} \right) \\
+ \sum_{\ell=2}^{k-1} \left( 1 + \binom{k - \ell - \chi_1}{k - \ell} \binom{\ell - 1 - \chi_2}{\ell - 1} \right) - 2k \\
= 1 - \sum_{\ell=0}^{k} \binom{k - \ell - \chi_1}{k - \ell} \binom{\ell - 1 - \chi_2}{\ell} = 1 - \binom{k - \chi_1 - \chi_2}{k}.
\]
The last identity can be verified directly, or found in [10, (1.78)]. This completes this cute argument and the proof of Proposition 5.1. □

5.2. Euler characteristic of \(B^Q_p(X)\) for \(X\) disconnected. We extend the previous computation to the barycenter space with singular weights and to the Euler characteristic with compact supports. Here too we show that the final answer doesn’t differ from the connected case. Starting with the stratification of \(B^Q_p(X)\) in (4.5), valid for all \(X\), we follow the steps in the proof of Proposition 4.5. Only one step needs to be modified which is the identification in Lemma 4.3 which is no longer true if \(X\) is disconnected. The correct identification in that case is given by the following lemma.

**Lemma 5.4.** Let \(X\) be a disjoint union of components \(A_i\), which are locally closed in \(\overline{A}_i\), and of compact components \(B_j\). We write
\[
X = \bigsqcup_{i=1}^{q} A_i \sqcup \bigsqcup_{j=1}^{t} B_j.
\]
Assume without loss of generality that \(A_1, \ldots, A_s\) have singular points each of respective cardinality \(a_1, \ldots, a_s \neq 0\). Assume as well that \(B_1, \ldots, B_t\) have each singular points of respective cardinality \(b_1, \ldots, b_t \neq 0\). Obviously \(a_1 + \ldots + a_s + b_1 + \ldots + b_t = r\). The other components \(A_{s+1}, \ldots, A_q, B_{t+1}, \ldots, B_t\) have no singular points. Then
\[
\frac{X}{\partial X \sqcup Q_r} \simeq \left( \frac{\partial A_1}{\partial A_1} \vee \cdots \vee \frac{\partial A_q}{\partial A_q} \vee B_1 \vee \cdots B_{t} \vee \bigvee_{r-\ell} S^1 \right) \bigcup B_{t+1} \sqcup \cdots \sqcup B_t.
\]
**Proof.** Each component \(B_i\) with \(b_i\) singular points contributes a bouquet \(b_i^{-1} S^1\) in the quotient. Since \(\partial X = \bigsqcup \partial \overline{A}_i\), each component \(A_j\) with \(a_j\) singular points contributes a bouquet of \(\bigvee S^1\) in the quotient (the extra leaf in the bouquet comes from the fact that there is non-trivial boundary, see Lemma 4.3). Since \(a_1 + \ldots + a_s + b_1 - 1 + \ldots b_t - 1 = r - \ell\), this accounts for the bouquet of circles and the rest is immediate. □
Remark 5.5. We can double-check this decomposition against the computation $\chi_c(X - Q_r) = \chi_c(X) - r$. Indeed, let’s recall that

$$\chi(Z_1 \vee \ldots \vee Z_n \vee \bigvee^m S^1) = \sum \chi(Z_i) - (n + m - 1).$$

We have

$$\chi\left(\frac{X}{\partial X \cup Q_r}\right) = \sum_{i=1}^q \chi\left(\frac{A_i}{\partial A_i}\right) + \sum_{j=1}^\ell \chi(B_1) - (q + \ell + r - \ell - 1) + \sum_{j=\ell+1}^t \chi(B_j)$$

$$= \sum_{i=1}^q (\chi_c(A_i) + 1) + \sum_{j=1}^t \chi(B_j) - q - r + 1 = \chi_c(X) - r + 1,$$

where $\chi_c(X) = \sum \chi_c(A_i) + \sum \chi(B_i)$. This gives that

$$\chi_c(X - Q_r) = \chi\left(\frac{X}{\partial X \cup Q_r}\right) - 1 = \chi_c(X) - r$$
as expected.

**Theorem 5.6.** *Theorem 1.1 is true if $X$ is disconnected.*

**Proof.** As in the proof of Proposition 4.5, we use the same stratification of $B^\rho_{Q^r}(X)$ with generic stratum $X_n$. By taking the appropriate compactification and applying both Lemmas 5.1, 5.4 and Remark 5.5, we obtain that

$$\chi_c(X_n) = (-1)^n \left(\chi^n_1 X_1 \frac{X}{\partial X \cup Q_r} - 1\right) = -(-1)^n \left(\frac{n - \chi_c + r - 1}{n}\right),$$

which is the same as in the connected case. The rest of the argument runs as in the proof in Section 4.1.

### 6. The case of two singular points

Interestingly, even though the distribution of the singular points among the components doesn’t affect the Euler characteristic, it does greatly affect the homology. We analyze completely the various homotopy types (depending on weights) of the space $B^\rho_{Q^2}(X)$ with $X$ having at most two connected components (this can easily be extended to any number of components).

**Proposition 6.1.** *Suppose $X$ is connected, $0 < w_1 \leq w_2 \leq 1$. Write $\rho = \lfloor \rho \rfloor + \varepsilon$, $0 \leq \varepsilon < 1$, and $n = \lfloor \rho \rfloor$. Then the possible homotopy types of $B^\rho_{Q^2}(X)$ are:

(a) contractible, if $0 < w_1 + w_2 \leq \varepsilon$,
(b) $\Sigma B_n(X \vee S^1)$, if $w_1 \leq \varepsilon, w_2 \leq \varepsilon, w_1 + w_2 > \varepsilon$,
(c) contractible, if $w_1 \leq \varepsilon, w_2 > \varepsilon$,
(d) $B_n(X \vee S^1)$, if $w_1 > \varepsilon, w_2 > \varepsilon, w_1 + w_2 \leq 1 + \varepsilon$,
(e) $B_n(X)$, if $w_1 + w_2 > 1 + \varepsilon$.*
singular points with weights $w$ which is contractible (Lemma 2.2).

(b) This is the case when $B_{\rho}^{Q_2}(X) = B_n(X, p_1) \cup B_n(X, p_2)$. This union was worked out in the proof of Proposition 5.1 and is of the homotopy type of $\Sigma B_n(X/p_1 \sim p_2) \simeq \Sigma B_n(X \vee S^1)$.

(c) This is the case $B_{\rho}^{Q_2}(X) = B_n(X, p_1)$, and is contractible.

(d) This is the case $B_{\rho}^{Q_2}(X) = B_n(X) \cup B_{n-1}(X, p_1, p_2)$ which is up to homotopy $B_n(X \vee S^1)$.

(e) This is immediate. \hfill \Box

Turning to the disconnected case, we can write $X = A_1 \sqcup \ldots \sqcup A_q$ as a disjoint union of non-empty connected components. As before $Q_r = \{p_1, \ldots, p_r\}$ are the singular points with weights $w_1, \ldots, w_r$. Let’s write $B_{\rho}^{Q_r}(X)$ in the form

\begin{equation}
B_{\rho}^{Q_1, \ldots, Q_q}(X)
\end{equation}

indicating the location of the singular points $r_i$ of which are in $A_i$, $\sum r_i = r$.

**Proposition 6.2.** Let $X = A_1 \sqcup A_2$, $r = 2$.

(a) Suppose $0 < [\rho] + w_1 + w_2 \leq \rho$. Then

$$B_{\rho}^{Q_1}(X) \simeq B_{\rho}^{Q_2, \rho}(X) \simeq B_{[\rho]}(X, p_1, p_2) \simeq \ast.$$  

(b) $0 < [\rho] + w_1, [\rho] + w_2 \leq \rho, [\rho] + w_1 + w_2 > \rho$. Then

$$B_{\rho}^{Q_1}(X) \simeq \Sigma B_{[\rho]}(A_1 \vee A_2), \quad B_{\rho}^{Q_2, \rho}(X) \simeq \Sigma B_{[\rho]}(A_1 \vee S^1 \sqcup A_2).$$

(c) Suppose $0 < [\rho] + w_1 \leq \rho, [\rho] + w_2 > \rho$. Then

$$B_{\rho}^{Q_1}(X) \simeq \ast \simeq B_{\rho}^{Q_2, \rho}(X).$$

(d) Suppose $\rho < [\rho] + w_1, [\rho] + w_2, [\rho] + w_1 + w_2 \leq 1 + \rho$. Then

$$B_{\rho}^{Q_1}(X) \simeq B_{[\rho]}(A_1 \vee A_2), \quad B_{\rho}^{Q_2, \rho}(X) \simeq B_{[\rho]}(A_1 \vee S^1 \sqcup A_2).$$

(e) Suppose $\rho < [\rho] + w_1, [\rho] + w_2 \leq 1 + \rho, [\rho] + w_1 + w_2 > 1 + \rho$. Then

$$B_{\rho}^{Q_1}(X) = B_{[\rho]}(X) = B_{\rho}^{Q_2, \rho}(X).$$

**Proof.** The proof runs exactly as in the previous proposition keeping track of the identifications in $B_n(X/p_1 \sim p_2)$ as in Lemma 5.4. \hfill \Box

**Acknowledgements.** This paper answers a question of A. Malchiodi who conjectured Corollary 1.8. We are grateful to him for sharing his question and insight.
